# **High Performance Computing**

# Ionospheric Radar Returns Classification using SGD

Details-

Sujoy Datta (CED18I063) Sem 7(4th year)- CSE Dual Degree

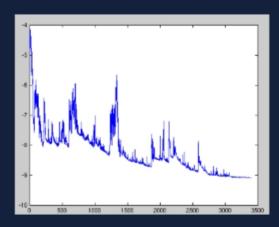

### Relevance

The Ionosphere is at the horizon of the atmosphere and outer space.
Interestingly, Ionosphere exploration falls into the category of Solar System Exploration.

The ionosphere is the ionized part of the Earth's atmosphere from 48 km to 965 km, which includes the thermosphere and parts of the mesosphere and exosphere.

In lonospheric research, we need to classify the signals as useful(good) or useless(bad) for further analysis.

Fluctuations in the total objective function as gradient steps with respect to mini-batches are taken.

### Addressable Problem Statement

Classifying signals based on high frequency antenna responses and determining line of best fit using parallel computing.

Evaluating the sum-gradient may require expensive evaluations of the gradients from all summand functions. Parallelising this operation can improve computational time.

# Stochastic Gradient Descent Algorithm

Both statistical estimation and machine learning consider the problem of minimizing an objective function that has the form of a sum. Evaluating the sum-gradient may require expensive evaluations of the gradients from all summand functions. Parallelising this operation can improve computational time.

Gradient descent is an iterative algorithm that starts from a random point on a function and travels down its slope in steps until it reaches the lowest point of that function. Iteration mechanism is sigmoid.

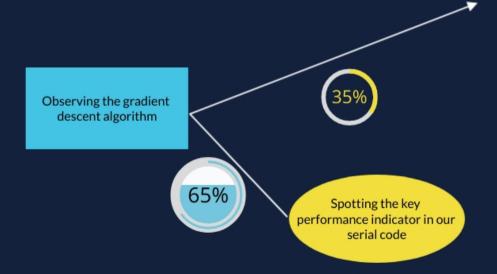

For a dataset with r feature dependencies the line of best fit can be determined using the stochastic gradient descent algorithm. The value of constants [b][0...r] can be calculated using a fixed learning rate and predicted initial values. The summinimization problem also arises for empirical risk minimization.

$$p(\mathbf{x}) = \frac{1}{1 + \exp(-f(\mathbf{x}))}$$
$$f(\mathbf{x}) = b_0 + b_1 x_1 + \dots + b_r x_r$$

# Why use SDG for Ionospheric Regression?

Stochastic gradient descent (often abbreviated SGD) is an iterative method for optimizing an objective function with suitable smoothness properties.

So, in SGD, we find out the gradient of the cost function of a single example at each iteration instead of the sum of the gradient of the cost function of all the examples.

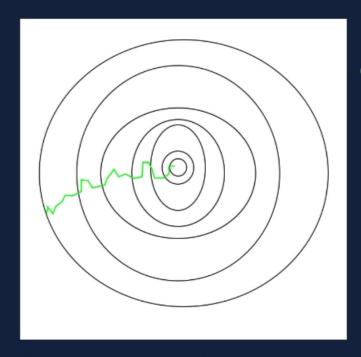

# Classification of Radar Returns

Received signals were processed using an autocorrelation function whose arguments are the time of a pulse and the pulse number. There were 17 pulse numbers for the Goose Bay system. Instances in this database are described by 2 attributes per pulse number, corresponding to the complex values returned by the function resulting from the complex electromagnetic signal.

The Goose Bay Laboratory has 34 high frequency antennas that detect the probability of free electrons present in the atmosphere. For the ionospheric classification we can use the exploratory data analysis to determine the most influential data features.

for i in range (m):  

$$\theta_{j} = \theta_{j} - \alpha (\hat{y}^{i} - y^{i}) x_{j}^{i}$$

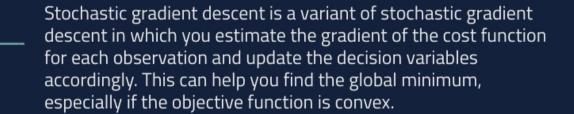

### Algorithm

This is the crux of the algorithm. The general idea is to start with a random point (in our parabola example start with a random "x") and find a way to update this point with each iteration such that we descend the slope.

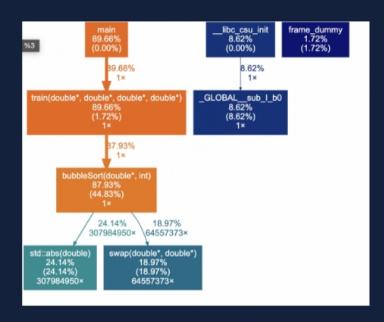

The steps of the algorithm are

- Find the slope of the objective function with respect to each parameter/feature. In other words, compute the gradient of the function.
- Pick a random initial value for the parameters. (To clarify, in the parabola example, differentiate "y" with respect to "x". If we had more features like x1, x2 etc., we take the partial derivative of "y" with respect to each of the features.)
- Update the gradient function by plugging in the parameter values.
- Calculate the step sizes for each feature as: step size = gradient \* learning rate.
- Calculate the new parameters as : new params = old params step size
- Repeat steps 3 to 5 until gradient is almost 0.

### Serial Code Block

# **Functional Profiling**

It displays the executed code in a visual diagram where each node corresponds to a function or method and their relations show the code flow.

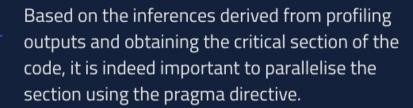

# Line Profiling

17550:	62:	b0 = b0 - alpha
17550:	63:	b1 = b1 + alpha
17550:	64:	b2 = b2 + alpha
17550:	65:	b3 = b3 + alpha
-:	66:	

Profiling allows us to learn where the program spent its time and which functions called which other functions while it was executing. This information can show which pieces of the program are slower than expected

## Parallelising SGD

The preprocessor directive #pragma is used to provide the additional information to the compiler in C/C++ language. This is used by the compiler to provide some special features.

```
start=omp_get_wtime();
#pragma omp parallel for
for (i = 0; i < 10530; i++)
   idx = i % 10;//for accessing index after every batch
   p[i] = -(b[0][i] + b[1][i] * x1[idx] + b[2][i] * x2[idx] + b[3][i] * x3[idx]); //making the prediction
   pred[i] = 1 / (1 + pow(e, p[i])); //calculating final prediction applying sigmoid
    err[i] = y[idx] - pred[i]; //calculating the error
   for(int j=0;j<100000;j++)
       b[0][i]=b[0][i] - alpha * err[i] * pred[i] * (1 - pred[i]) * 1.0;
       b[1][i]=b[1][i] + alpha * err[i] * pred[i] * (1 - pred[i]) * x1[idx]; //updating b1
       b[2][i]=b[2][i] + alpha * err[i] * pred[i] * (1 - pred[i]) * x2[idx]; //updating b2
       b[3][i]=b[3][i] + alpha * err[i] * pred[i] * (1 - pred[i]) * x3[idx]; //updating b3
    //cout << "\tB0= " << b[0][i] << " " << "\t\tB1= " << b[1][i] << " " t\tB2= " << b[2][i] << "\t\tB3= " << b[3][i] << "\t\tError=" << endl;
    error[i]=err[i];
bubbleSort(error,i);
//custom sort based on absolute error difference
end=omp_get_wtime();
```

# Observational Tabulation

150	0.19512	2.52572775727757	60.8128701305104

Speed up can be found using the following formula,

S(n)=T(1)/T(n)

where, S(n) = Speedup for thread count 'n'

T(1) = Execution Time for Thread count '1' (serial code)

T(n) = Execution Time for Thread count 'n' (serial code)

Parallelization Fraction can be found using the following formula,

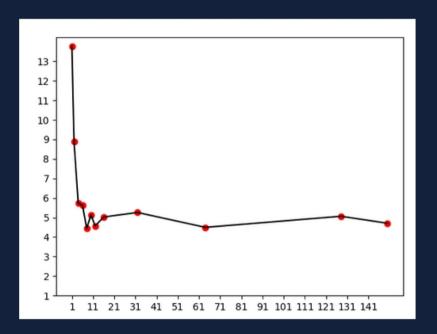

S(n)=1/((1-p)+p/n)

where, S(n) = Speedup for thread count 'n'

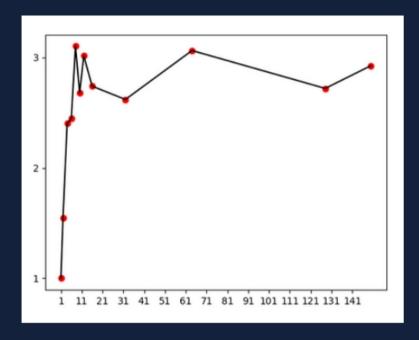

n = Number of threads

p = Parallelization fraction

# # Threads vs Execution Time

# #Threads vs Speed-up

### Inferences-

- At thread count 64 maximum speedup is observed
- If thread count is more than 64 then the execution time increases slightly and tapers out.

# Ionospheric Radar Returns Classification using SGD

**High Performance Computing Project Report** 

**Problem Statement**: Classifying signals based on high frequency antenna responses and determining line of best fit using parallel computing.

Faculty Guide: Dr. Noor Mahammad

Ву,

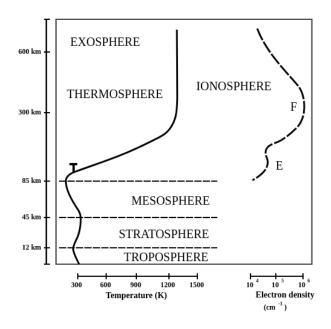

Sujoy Datta CED18I063

### Introduction

The lonosphere is at the horizon of the atmosphere and outer space. Interestingly, lonosphere exploration falls into the category of Solar System Exploration. The ionosphere is the ionized part of the Earth's atmosphere from 48 km to 965 km, which includes the thermosphere and parts of the mesosphere and exosphere.

Reasons to classify signals for the lonosphere-

- 1. It houses all the charged particles of the Earth's atmosphere.
- 2. It is the boundary between Earth's atmosphere and space.
- 3. The orbital drag is felt in this region.
- 4. The favourite hangout place for our Earth Orbiting satellites.
- 5. It's influenced by fluctuations in our weather conditions on Earth.
- 6. Radio and GPS signals are disrupted by radiation in the lonosphere.
- 7. Influenced by weather conditions in space.

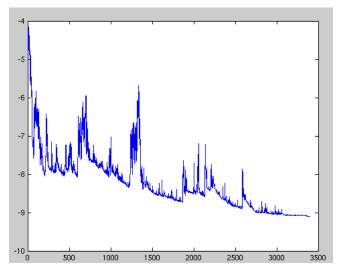

In lonospheric research, we need to classify the signals as useful(good) or useless(bad) for further analysis. Often in such analysis manual intervention is necessary and it's a painful time-consuming task. The John Hopkins Applied Physics Laboratory has made the data collected from Goose Bay, Labrador radar in the UCI machine learning repository.

This problem from the Geophysics domain can be mapped into a binary classification problem in Machine learning.

# **Stochastic Gradient Descent Algorithm**

Both statistical estimation and machine learning consider the problem of minimizing an objective function that has the form of a sum. Evaluating the sum-gradient may require expensive evaluations of the gradients from all summand functions. Parallelising this operation can improve computational time.

Fluctuations in the total objective function as gradient steps with respect to mini-batches.

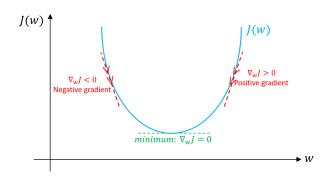

Gradient descent is an iterative algorithm that starts from a random point on a function and travels down its slope in steps until it reaches the lowest point of that function. Iteration mechanism is sigmoid.

### **Mathematical Formula-**

$$p(\mathbf{x}) = \frac{1}{1 + \exp(-f(\mathbf{x}))}$$
$$f(\mathbf{x}) = b_0 + b_1 x_1 + \dots + b_r x_r$$

For a dataset with r feature dependencies the line of best fit can be determined using the stochastic gradient descent algorithm. The value of constants [b][0...r] can be calculated using a fixed learning rate and predicted initial values. The sum-minimization problem also arises for empirical risk minimization.

## Why use SDG for lonospheric Regression?

### Relevance

- Stochastic gradient descent (often abbreviated SGD) is an iterative method for optimizing an objective function with suitable smoothness properties.
   So, in SGD, we find out the gradient of the cost function of a single example at each iteration instead of the sum of the gradient of the cost function of all the examples.
- 2. It can be regarded as a stochastic approximation of gradient descent optimization. In SGD, since only one sample from the dataset is chosen at random for each iteration, the path taken by the algorithm to reach the minima is usually noisier than your typical Gradient Descent algorithm.
- 3. Especially in high-dimensional optimization problems this reduces the computational burden, achieving faster iterations in trade for a lower convergence rate. But that doesn't matter all that much because the path taken by the algorithm does not matter, as long as we reach the minimum and with significantly shorter training time.

### **Classification of Radar Returns**

This radar data is collected by a system in Goose Bay, Labrador. The system consists of a phased array of 16 High-frequency antennas with a total transmission power of 6.4 kilowatts. The targets were free electrons in the ionosphere.

Received signals were processed using an autocorrelation function whose arguments are the time of a pulse and the pulse number. There were 17 pulse

numbers for the Goose Bay system. Instances in this database are described by 2 attributes per pulse number, corresponding to the complex values returned by the function resulting from the complex electromagnetic signal.

The Goose Bay Laboratory has 34 high frequency antennas that detect the probability of free electrons present in the atmosphere. For the ionospheric classification we can use the exploratory data analysis to determine the most influential data features.

1	0.23188	0	b

Received signals were processed using an autocorrelation function whose arguments are the time of a pulse and the pulse number. There were 34 high freq antennas for the Goose Bay system.

### **Algorithm**

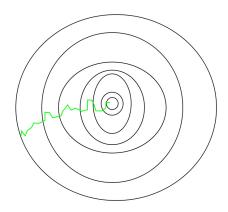

This is the core part of the problem. The general idea is to start with a random point (in our parabola example start with a random "x") and find a way to update this point with each iteration such that we descend the slope.

for i in range (m):  

$$\theta_{i} = \theta_{i} - \alpha (\hat{y}^{i} - y^{i}) x_{i}^{i}$$

The steps of the algorithm are

- 1. Find the slope of the objective function with respect to each parameter/feature. In other words, compute the gradient of the function.
- 2. Pick a random initial value for the parameters. (To clarify, in the parabola example, differentiate "y" with respect to "x". If we had more features like x1, x2 etc., we take the partial derivative of "y" with respect to each of the features.)
- 3. Update the gradient function by plugging in the parameter values.
- 4. Calculate the step sizes for each feature as : step size = gradient \* learning rate
- 5. Calculate the new parameters as: new params = old params -step size
- 6. Repeat steps 3 to 5 until the gradient is almost 0.

Path taken by Stochastic Gradient Descent

### **Softwares**

- 1. C/C++, programming language
- 2. OpenMP, API for shared-memory parallel programming
- 3. MPI, High performance Message Passing library
- 4. Cuda C/C++, API for utilizing CUDA-enabled GPU for computation

### **Core Meaning**

Stochastic gradient descent algorithms are a modification of gradient descent. In stochastic gradient descent, you calculate the gradient using just a random small

part of the observations instead of all of them. In some cases, this approach can reduce computation time.

Online stochastic gradient descent is a variant of stochastic gradient descent in which you estimate the gradient of the cost function for each observation and update the decision variables accordingly. This can help you find the global minimum, especially if the objective function is convex.

# Serial Code (C++)

```
#include <bits/stdc++.h>
#include <iostream>
#include <string>
#include <iomanip>
#include <omp.h>
#include <sstream>
#include <fstream>
using namespace std;
//Variables for obtaining line of best fit
double b[4][10530]={};
//Swapping function
void swap(double *xp, double *yp)
{
    double temp = *xp;
    *xp = *yp;
    *yp = temp;
}
// A function to implement bubble sort
void bubbleSort(double arr[], int n)
    int i, j;
    for (i = 0; i < n-1; i++)
    //Absolute swapping mechanism
    for (j = 0; j < n-i-1; j++)
        if (abs(arr[j]) > abs(arr[j+1]))
            swap(&arr[j], &arr[j+1]);
}
```

```
//Training using the obtained data set
void train(double *x1,double *x2,double *x3,double *y)
{

### **Functional Profiling-**

Profiling allows us to learn where the program spent its time and which functions called which other functions while it was executing. This information can show which pieces of the program are slower than expected, and might be candidates for rewriting to make the program execute faster. It can also tell which functions are being called more or less often than expected. This may help to spot bugs that had otherwise been unnoticed.

Since the profiler uses information collected during the actual execution of the program, it can be used on programs that are too large or too complex to analyze by reading the source. However, how the program is run will affect the information that shows up in the profile data. If we don't use some feature of the program while it is being profiled, no profile information will be generated for that feature.

### Steps to profile-

Step 1. Enable profiling during compilation (use -pg option) \$ gcc -pg -o TestGprof TestGprof.c

Step 2. Execute the binary so that profiling data is generated \$ ./TestGprof

Step 3. If the profiling is enabled then on executing the program, file gmon.out will be generated.

\$ Is gmon.out TestGprof TestGprof.c

# 1. Flat Profile (Excluding the built-in STL functions)

% time	Cumulative seconds	Self Seconds	Calls	Self ms/call	Total ns/call	Name
1.79	0.26	0.01	1	260.72	501.38	bubbleSort(dou ble*, int)
18.80	0.50	0.11	64557373	0.00	0.00	swap(double*, double*)
8.06	0.55	0.05	1	45.12	45.12	_GLOBALsub_I _b0
46.56	0.56	0.26	1	10.03	511.40	train(double*, double*, double*, double*)
0.90	0.56	0.01				frame_dummy
0.00	0.56	0.00	1	0.00	0.00	test(double, double, double)

### Terminology-

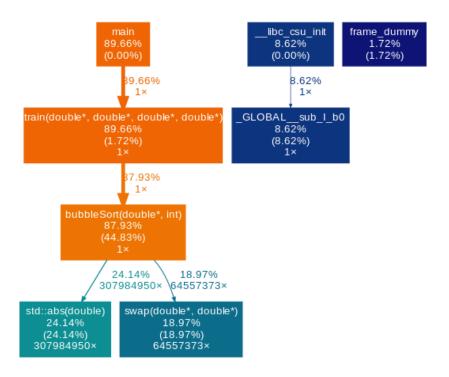

- 1. % time- the percentage of the total running time of the program used by this function.
- 2. Cumulative seconds- a running sum of the number of seconds accounted for by this function and those listed above it.
- 3. self seconds- the number of seconds accounted for by this function alone. This is the major sort for this listing.
- 4. Calls- the number of times this function was invoked, if this function is profiled, else blank.

12

- 5. self ms/call- the average number of milliseconds spent in this function per call, if this function is profiled, else blank.
- 6. Total ms/call- the average number of milliseconds spent in this function and its descendents per call, if this function is profiled, else blank.
- 7. Name- the name of the function. This is the minor sort for this listing. The index shows the location of the function in the gprof listing. If the index is in parenthesis it shows where it would appear in the gprof listing if it were to be printed.

### 2. Functional Graph Diagram-

It displays the executed code in a visual diagram where each node corresponds to a function or method and their relations show the code flow.

## **Line Profiling Output-**

Line profiling is a process where we analyze time taken by various parts of our code for every line of the code. It can help us better understand the time/space complexity of our code.

### 2. Architectural Capability-

- 1. This architecture has 27 counters.
- 2. This architecture has 439 events.

```
This architecture has 27 counters.
Counter tags(name, type<, options>):
FIXCO, Fixed counters, KERNEL|ANYTHREAD
FIXC1, Fixed counters, KERNEL|ANYTHREAD
FIXC2, Fixed counters, KERNEL|ANYTHREAD
PMCO, Core-local general purpose counters,
```

```
This architecture has 439 events.
Event tags (tag, id, umask, counters<, options>):
TEMP_CORE, 0x0, 0x0, TMP0
PWR_PKG_ENERGY, 0x2, 0x0, PWR0
PWR_PP0_ENERGY, 0x1, 0x0, PWR1
PWR_PP1_ENERGY, 0x4, 0x0, PWR2
PWR_DRAM_ENERGY, 0x3, 0x0, PWR3
```

### Inferences-

### 1. Extent of Parallelism

Task parallelism (also known as function parallelism and control parallelism) is a form of parallelization of computer code across multiple processors in parallel computing environments. Task parallelism focuses on distributing tasks—concurrently performed by processes or threads—across different processors. In contrast to data parallelism which involves running the same task on different components of data, task parallelism is distinguished by running many different tasks at the same time on the same data.

A common type of task parallelism is multi-threading which consists of moving a single set of data through a series of separate tasks where each task can execute independently of the others. In the above serial code we look into the following aspects-

a. Task parallelism- choosing the task with the maximum wall clock serial time. Task parallelism emphasizes the distributed (parallelized) nature of the processing (i.e. threads), as opposed to the data (data parallelism). Most real programs fall somewhere on a continuum between task parallelism and data parallelism.

In the training function above, a considerable distributed nature can be observed.

### **Critical Code to parallelise-**

```
for (i = 0; i < 10530; i++)
  {
     idx = i % 10;//for accessing index after every batch
     p[i] = -(b[0][i] + b[1][i] * x1[idx] + b[2][i] * x2[idx] + b[3][i] * x3[idx]);//making
the prediction
     pred[i] = 1 / (1 + pow(e, p[i])); //calculating final prediction applying sigmoid
     err[i] = y[idx] - pred[i]; //calculating the error
     for(int j=0;j<100000;j++)
     {
       b[0][i]=b[0][i] - alpha * err[i] * pred[i] * (1 - pred[i]) * 1.0; //updating b0
       b[1][i]=b[1][i] + alpha * err[i] * pred[i] * (1 - pred[i]) * x1[idx]; //updating b1
       b[2][i]=b[2][i] + alpha * err[i] * pred[i] * (1 - pred[i]) * x2[idx]; //updating b2
       b[3][i]=b[3][i] + alpha * err[i] * pred[i] * (1 - pred[i]) * x3[idx]; //updating b3
     }
     //cout << "\tB0= " << b[0][i] << " " << "\t\tB1= " << b[1][i] << " " << "\t\tB2= "
<< b[2][i] << "\t\tB3= " << b[3][i] << "\t\tError=" << err << endl;
     error[i]=err[i];
  }
```

 Motivational Pseudocode to push parallelismprogram:

```
if CPU = "a" then
do task "A"
else if CPU="b" then
do task "B"
end if
...
end program
```

### 2. Functional modularity

Profiling is normally useful only after we've detected that something is wrong with our program. However, it could still be performed before that even happens to catch possible unseen bugs, which would, in turn, help chip away the time spent debugging the application at a later stage. Observations-

a. On observing the total ms/call value for all the rows in the flat profile, it is quite evident that the most amount of time spent is on this functional module. The thread level parallelism implemented on this function can assist in saving the corresponding serial execution time frame.

46.56	0.56	0.26	1	10.03	511.40	train(double*, double*, double*, double*)
-------	------	------	---	-------	--------	--

b. **Line Profiling** can help avoid that **crash and burn outcome**, since it provides a fairly accurate view of what our program is doing(line-by-line), no matter the load. So, if we profile it with a very light load, and the result is that we're spending 80 percent of our time doing some kind of I/O operation, it might raise a flag for us.

### Code piece-

```
17550: 62: b0 = b0 - alpha * err * pred * (1 - pred) * 1.0; //updating b0
17550: 63: b1 = b1 + alpha * err * pred * (1 - pred) * x1[idx]; //updating b1
17550: 64: b2 = b2 + alpha * err * pred * (1 - pred) * x2[idx]; //updating b2
17550: 65: b3 = b3 + alpha * err * pred * (1 - pred) * x3[idx]; //updating b3
```

### 3. Processor Utilisation-

The least upper bound imposed upon processor utilization by the requirement for real-time guaranteed service can approach in big order of magnitudes for large task sets. It is desirable to find ways to improve this situation, since the practical costs of switching between tasks must still be counted.

a. Cache comparison- All processors rely on L1 cache, this is usually located on the die of the processor and is very fast memory (and expensive). L2 cache is slower, bigger and cheaper than L1 cache.

- Older processors used L2 cache on the motherboard, nowadays it tends to be built into the processor. L3 cache is slower, bigger and cheaper than L2 cache.
- b. Many processes have known functions and durations(CPI\_STATS) and can be given a permanent, fixed priority. In process control applications, where the duration and function of each process is known at design time, it may be appropriate to assign processes fixed priorities and place them in a static order. In this case, the scheduler begins at the top of the queue of processes and searches down for the first runnable process.
- c. In designing schedulers for cache blocks and processors, it is important to determine the desirable criteria for a scheduler. The low-level scheduler basically determines which task has the highest priority and then selects that task for execution; it also maintains the ready queue.

### **Parallelising SGD**

The preprocessor directive #pragma is used to provide the additional information to the compiler in C/C++ language. This is used by the compiler to provide some special features.

### Approach-

Based on the inferences derived from profiling outputs and obtaining the critical section of the code, it is indeed important to parallelise the section using the pragma directive.

### Code(C++)

```
#include <bits/stdc++.h>
#include <iostream>
#include <string>
#include <iomanip>
#include <omp.h>
#include <sstream>
#include <fstream>
using namespace std;
//Variables for obtaining line of best fit
```

```
double b0=0, b1=0, b2=0, b3=0;
//Swapping function
void swap(double *xp, double *yp)
{
    double temp = *xp;
    *xp = *yp;
    *vp = temp;
}
string convertToString(char* a, int size)
{
    int i;
    string s = "";
    for (i = 0; i < size; i++) {
        s = s + a[i];
    return s;
}
// A function to implement bubble sort
void bubbleSort(double arr[], int n)
{
    int i, j;
    for (i = 0; i < n-1; i++)
    //Absolute swapping mechanism
    for (j = 0; j < n-i-1; j++)
        if (abs(arr[j]) > abs(arr[j+1]))
            swap(&arr[j], &arr[j+1]);
}
//Training using the obtained data set
void train(double x1[351],double x2[351],double x3[351],double
y[351])
{
    double start,end;
    int i,idx=0;double error[5616]; // for storing the error values
    //Since there are 351 values in our dataset and we want to run
for 50 batches so total for loop run 17550 times
    double err=y[0]-0.5;  // for calculating error on each
```

```
stage
    double alpha = 0.01; // initializing our learning rate
    double p;
    double e = 2.718281828,pred=0;
    start=omp get wtime();
    #pragma omp parallel for private(b0,b1,b2,b3,p)
    for(idx=0;idx<=16;idx++)</pre>
    {
        for (i = 0; i < 351; i++)
            p = -(b0 + b1*x1[idx] + b2*x2[idx] + b3*x3[idx]);//making
the prediction
            pred = 1 / (1 + pow(e, p));

### **Theoretical Background**

1. Speed up can be found using the following formula,

$$S(n)=T(1)/T(n)$$

where, S(n) = Speedup for thread count 'n'

T(1) = Execution Time for Thread count '1' (serial code)

T(n) = Execution Time for Thread count 'n' (serial code)

2. Parallelization Fraction can be found using the following formula,

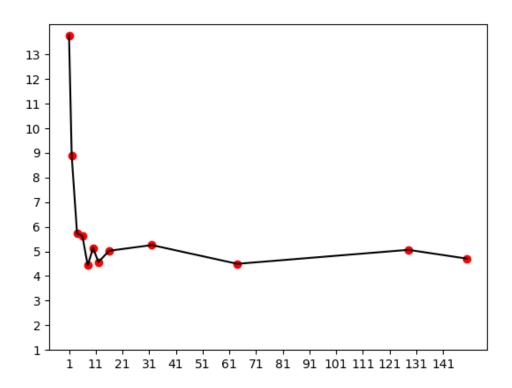

$$S(n)=1/((1 - p) + p/n)$$

where, S(n) = Speedup for thread count 'n'

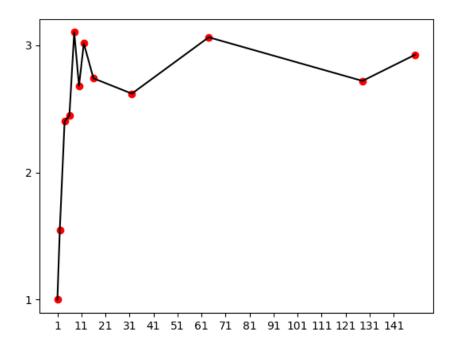

n = Number of threads

p = Parallelization fraction

# **Graphical Analysis**

# Threads vs Execution Time

**#Threads vs Speed-up** 

### Inferences-

- At thread count 64 maximum speedup is observed
- If thread count is more than 64 then the execution time increases slightly and tapers out.
